

### Spectroscopic methods:

- Supersonic jet-cooling
- Laser induced fluorescence (LIF)
- IR-UV double resonance spectroscopy

#### Molecular source:

#### Laser induced fluorescence

#### IR-UV double resonance spectroscopy

#### Advantages:

- cold species
- isolated species
- complexes formation

UV laser in resonance with electronic transition induces fluorescence (measurement of the ground state population)

infrared laser= pump  
excitation of vibrations in S<sub>0</sub>  
ultraviolet laser=probe  
probe of the population of the S<sub>0</sub> state.

Advantages: selectivity of the method

### Calculation strategy:

#### 1- Geometry optimisation of the isolated molecules

at MP2/6-31G\*\* level and charge distribution calculation. It is reduced to a set of Multipole (monopole, dipole and quadrupole) on each atom and one per chemical bond (Vigne-Maeder procedure).

#### 2- Interaction energy calculation (complexes geometries)

Claverie method further developed by V. Brenner (CEA Saclay)

Second order perturbation theory

Formal decomposition of the interaction energy

$$E = E_{\text{elec}} + E_{\text{rep}} + E_{\text{pol}} + E_{\text{disp}}$$

E<sub>elec</sub> multipole-multipole, E<sub>pol</sub> using experimental polarizability, E<sub>rep</sub> atom-atom contribution as well as for E<sub>disp</sub> which includes terms up to C<sub>10</sub>/R<sup>10</sup>

#### 3- Exploration of the potential energy surface

simulated annealing (global) followed by a local optimisation

#### 4- Ab Initio Calculations

B3LYP / 6-31G\*\* complete optimization

BSSE and harmonic frequencies calculation (\*0.96)

Optimisation of the "most significant" complexes at MP2/ 6-31G(d,p)

\*most significant\* = the most stable complexes calculated at B3LYP level + the structures which can undergo an important increase of the dissociation energy due to dispersion interactions

## Results

### Isolated molecules

#### (1R,2S)-cis-1-amino-2-indanol

#### Methyl lactate

### Experimental results

- Two complexes very similar for both diastereoisomers
- One vibrational structure for the heterochiral complex
- Rare features for homochiral complex

### Theoretical results

### Assignment

### Conclusion

- Two isomers clearly identified for both diastereoisomers

One of them is similar for RS and RR diastereoisomers :  
UV shift ~ 60 cm<sup>-1</sup> / IR : 3160 & 3500 cm<sup>-1</sup>  
assigned to **Insertion AI<sub>I</sub>-G**

- One RS diastereoisomer :

UV : vibrational progression in low energy region  
IR : 3351 & 3440 cm<sup>-1</sup>  
assigned to **Addition AI<sub>I</sub>-G**

- One RR diastereoisomer :

UV : single blue shifted band; IR : 3472 & 3505 cm<sup>-1</sup>  
assigned to **Cycle AI<sub>I</sub>-G**

- Clear discrimination between the two last complexes which evidence the major role of the CH...π interaction

- Very heavy calculations, especially if we want to increase the size of the system : We need for more accurate calculation methods : DFT-D, DFT-SAPT or "Return" to force fields (Anisotropic Polarizable Molecular Mechanics)
